

密码学基础实验报告

東北大學

实验名称 Vigenere 和 Column permutation cipher 的编程实现

班 级 软信-1503

学 号 20155362

姓 名 薛旗

日 期 2017.04.20

成 绩

评阅人

软件学院

一、实验目的与意义

实验目的：

- (1)通过编写程序设计实现古典密码体制中的 Vigenere Cipher, 并能够加密/解密一个字符串或文件；
- (2)通过编写程序设计实现古典密码体制中的 Column Permutation Cipher, 并能够加密/解密一个字符串或文件；
- (3)能够通过本实验了解古典密码的基本知识, 能够掌握算法的基本原理, 了解算法的详细步骤；

实验意义：

- (1)通过实践, 了解 Polyalphabetic Cipher 和 Transposition Cipher 的区别, 加深对古典密码体制的理解, 为深入学习密码学奠定基础；
- (2)通过实践, 不仅能够验证理论知识, 还能通过实践加强实验手段和实践技能, 培养分析问题、解决问题、应用知识的能力和创新能力, 提高综合素质。

二、实验环境

操作系统: Windows 10 专业版

调试软件: Microsoft Visual Studio Community 2017

版本号: 4.7.02046

上机地点: 信息学馆 B405

机器台号: 随机

三、实验的预习内容

Vigenere Cipher:

预习内容:

- (1)替代密码原理: 首先构造一个或多个密文字母表, 然后用密文字母表中的字母或字母组来代替明文字母或字母组, 各字母或字母组的相对位置不变, 但其本身改变了。这样编成的密码称为代替密码。按替代所使用的密文字母表的个数可将代替密码分为单表替代密码和多表替代密码。

Vigenere Cipher 属于多表替代密码。

- (2)Vigenere Cipher 数学表达式:

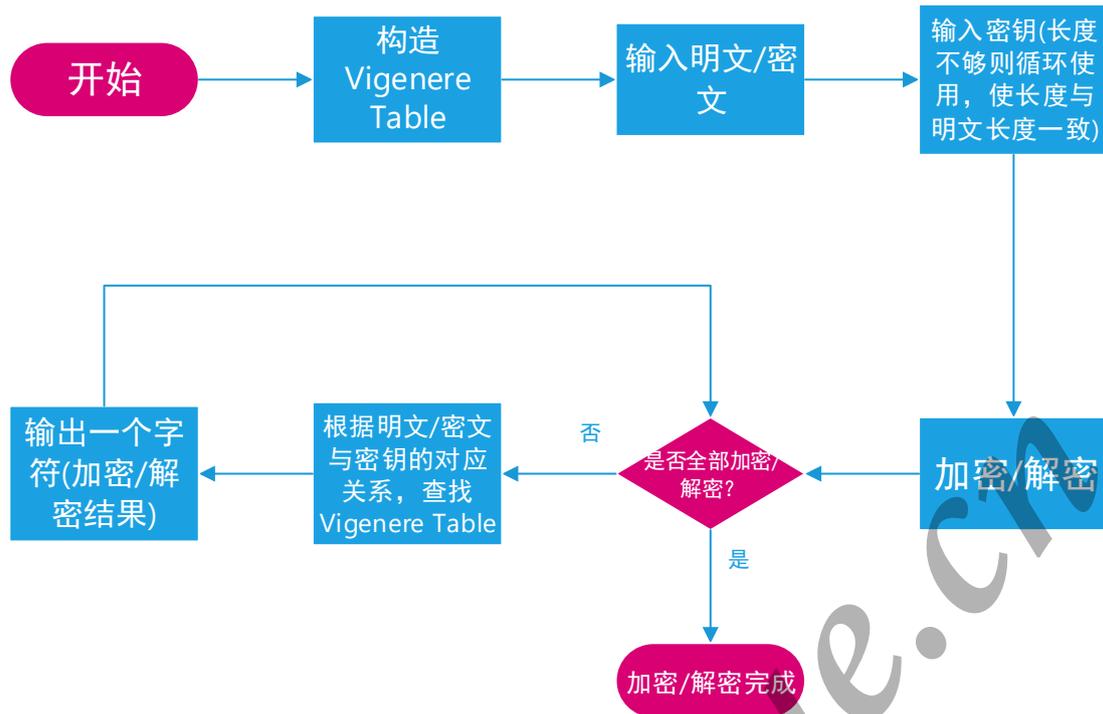

设 m 是一个正整数，定义 $P = C = K = (Z_{26})^m$ 对任意的密钥 $K = (k_1, k_2, \dots, k_m)$ ，定义 $e_K(x_1, x_2, \dots, x_m) = (x_1 + k_1, x_2 + k_2, \dots, x_m + k_m)$ 和 $d_K(y_1, y_2, \dots, y_m) = (y_1 - k_1, y_2 - k_2, \dots, y_m - k_m)$ ，以上所有运算都是在 Z_{26} 上进行。

(3)Vigenere Cipher 加密/解密原理：在一个具有密钥字长度为 m 的 Vigenere Cipher 中，一个字母可以被映射为 m 个字母中的某一个(假定密钥字包含 m 个不同的字母)。Vigenere Cipher 使用一个词组作为密钥，密钥中的每一个字母确定一个代替表，每一个密钥字母用来加密一个明文字母。等所有密钥字母都使用完后，密钥再循环使用。Vigenere Cipher 的替代规则是用明文字母在 Vigenere 方阵中的列和密钥字母在 Vigenere 方阵中的行的交点处的字母来代替该明文字母。其解密就是利用 Vigenere Table 进行反替代。

实验思路：

要实现对 Vigenere Cipher, 关键是找到对应关系。因此，其中最重要的一项工作是构造 Vigenere Table, 之后便可根据密钥与明文一一对应的关系在表中找对应的字符。假定密钥确定的是行替代表，那么密钥所确定的行和明文所确定的列的交叉位置处的字符，即为一个明文字符加密得到的密文字符。对于解密过程则与加密过程相反，由密钥先确定一个替代表（假定密钥确定的行替代表），然后在表中找到密文字符，密文字符所在列对应的字符即为明文。这里还需要注意的是密钥是循环使用的，密钥长度与明文一致。

程序框图：（见下页）

Column Permutation Cipher:

预习内容:

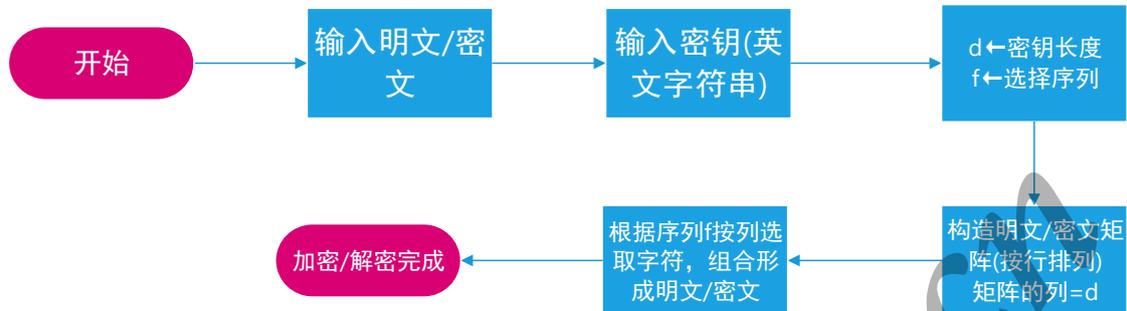

- (1) 置换密码原理: 把明文中的字母重新排列, 字母本身不变, 但其位置改变了, 这样编成的密码称为置换密码。置换密码又称为移位密码, 因为对照明文来看, 字母的位置被移动了。
- (2) Column Permutation Cipher 原理: Column Permutation Cipher 属于置换密码的一种, 其加密过程大致如下: 把明文按某一顺序排列成一个矩阵, 其中不足部分用符号 Φ 填充。然后按另一顺序选出矩阵中的字母以形成密文, 最后截成固定长度的字母组成密文。由加密过程可知, 改变矩阵的大小和选出顺序可以得到不同形式的密码。

实验思路:

要实现 Column Permutation Cipher 的加密/解密, 关键是构造明文/密文矩阵并能够得到一个合适的选出规则。在编程中通过输入一串英文字符来完成以上操作, 具体步骤为: 首先选用一串英文字符作为密钥, 构造的矩阵的列数与字符串长度保持一致, 明文/密文的长度不足以构造矩阵的则用 Φ 填充。按照字母的字典顺序给密钥字母编号, 对于重复的字母, 谁的位置靠前, 谁的编

号就靠前。于是我们就得到一组与密钥词语对应的数字序列。最后据此数字序列中的数字顺序按列选出明文/密文。

程序框图：

四、实验的步骤与调试方法

实验步骤：

步骤	说明	调用函数
1	编制标头	main()
2	加密/解密选择菜单	mainMenu()
3	算法选择菜单	menuOptions()
4	加密/解密方式(文件/键盘)	options()
5	字符检验(输入是否为纯英文)	Check(string s)
6	文件读取	readFileIntoString(char*)
7	打印 Vigenere Table	(*vigenereTable(char (&)[26][26])) [26]
8	Vigenere(键盘读取加密)	encyVigenereKeyboard()
9	Vigenere(键盘读取解密)	decryVigenereKeyboard()
10	Vigenere(文件读取加密)	encyVigenereFile()
11	Vigenere(文件读取解密)	decryVigenereFile()
12	Vigenere(加密主函数)	encyVigenere(string, string, char(*) [26])
13	Vigenere(解密主函数)	decryVigenere(string, string, char(*) [26])
14	Column(键盘读取加密)	encyColumnKeyboard()
15	Column(键盘读取解密)	decryColumnKeyboard()
16	Column(文件读取加密)	encyColumnFile()
17	Column(文件读取解密)	decryColumnFile()
18	Column(加密主函数)	encyColumn(string, string)
19	Column(解密主函数)	decryColumn(string, string)
20	Column 密钥构造	wordKey(string, int [20])

调试方法：

古典密码多为字符的替换和移位，故在调试过程中采用单步执行调试观察变量赋值，查找错误。在加密/解密过程中，可以先模拟选取一组简单的加密/解密字符，先通过人工验证，再通过程序实现，比较是否一致，从而能够快速发现问题，定位出错位置。具体调试步骤如下：

调试步骤:

- (1) 从错误的外部表现形式入手, 确定程序出错位置;
- (2) 研究相关程序, 找出错误原因;
- (3) 修改代码, 排除错误;
- (4) 重复进行测试, 观察错误是否修正。

五、实验数据与实验结果

Vigenere Cipher:

加密:

实验数据:

Plaintext: thisistheplaintext

Key: hold

加密结果:

Ciphertext: avtvpgekldwdpbeheh

实验结果展示(见下页):

七、思考题

1. Vigenere 密码的原理是什么?

答: Vigenere 是多表替代, 首先构造多个密文字母表, 然后用密文字母表中的字母来代替明文字母, 明文中的每一个字母都有多种可能的字母来代替。Vigenere 密码的代替规则是用明文字母在 Vigenere 方阵中的列和密钥字母在 Vigenere 方阵中的行的交叉点处的字母来代替该明文字母。

2. Vigenere 密码的主要缺陷有哪些?

答: Vigenere 密码使用循环的密钥进行加密。如果两个相同的明文段加密成两个相同的密文段, 它们的位置间距假设为 δ , 则 $\delta = 0 \pmod{m}$ 。反过来, 如果在密文中观察到两个相同的长度至少为 3 的密文段, 则他们对应了相同的明文串, 由此根据两个相同密文段间隔的距离可猜测出密钥长度, 这给破译者带来了很大的方便。

3. 对 Vigenere 密码的分析方法主要思想?

答: Kasiski 测试法: 搜索长度至少为 3 的相同密文段, 记下其离起始点的那个密文段的距离假如得到如下几个距离 $\delta_1, \delta_2, \dots$, 那么, 可以猜测 m 为这些 δ_i 的最大公因子的因子。

4. 对 Vigenere 密码的改进方法是什么?

答: 增加密钥长度, 减少密钥的循环使用。

5. Column permutation cipher 的原理是什么?

答: Column Permutation Cipher 属于置换密码的一种, 其原理如下: 把明文按行填充排列成一个矩阵, 其中不足部分用符号 Φ 填充。然后按预定顺序按列读取形成密文。

6. 给定关键字为 "experiment", 加密矩阵将包括几列, 以及列置换的次序是什么?

答: 加密矩阵将包括 10 列, 列置换次序为: 1-10-7-2-8-4-5-3-6-9。

7. Column permutation cipher 的安全性增强方法是什么?

答: 进行双重换位加密。先用列换位法将明文加密, 然后再次利用列换位法将第一次换位加密的密文加密。经过两次换位后, 明文字母的位置完全被打乱了, 从而可以增强安全性。

八、结束语

通过实践课程，我深入了解了 Polyalphabetic Cipher 和 Transposition Cipher 的区别，加深了我对古典密码体制的理解，在实践中不仅验证了理论知识，还加强了实验手段和实践技能，培养了我自主分析问题、解决问题、应用知识的能力和创新能力，受益匪浅。我认为实践课程对深入理解密码学的内涵有很大帮助，理论与实践相结合，对我的综合素质有很大的提升。同时，通过实践方式来学习古典密码，为以后学习现代密码奠定了很好的基础。

一、实验目的与意义

实验目的：

- (1)通过编写程序实现 DES 密码，并加密一个文件；
- (2)理解分组密码的基本理论；
- (3)掌握 DES 的基本原理，了解算法的详细步骤。

实验意义：

- (1)通过实践，亲自编程体验置换、替代、代数等多种密码技术的综合运用情况，体味 Shannon 所阐述的设计密码的思想；
- (2)通过实践，将理论知识与实践相结合，培养分析问题、解决问题、应用问题的能力，培养创新精神，提高综合素质。

二、实验环境

操作系统：Windows 10 专业版

调试软件：Microsoft Visual Studio Community 2017

版本号：4.7.02046

上机地点：信息学馆 B405

机器台号：随机

三、实验的预习内容

预习内容：

- (1)DES 简介：DES 是 Data Encryption Standard 的缩写，是美国国家标准局于 1977 年公布的由 IBM 公司研制的加密算法，并被作为非机要部门使用的数据加密标准。DES 算法是应用最广泛的一种分组密码算法，对密码理论的发展和应用起了重大作用。DES 综合运用了置换、代替、代数等多种密码技术，是面向二进制的密码算法，因而能够加解密任何形式的计算机数据。
- (2)DES 加密算法：DES 算法中数据以 64 比特分组进行加密，有效密钥长度为 56 位。它的加密算法与解密算法相同，只是解密子密钥与加密子密钥的使用顺序刚好相反。

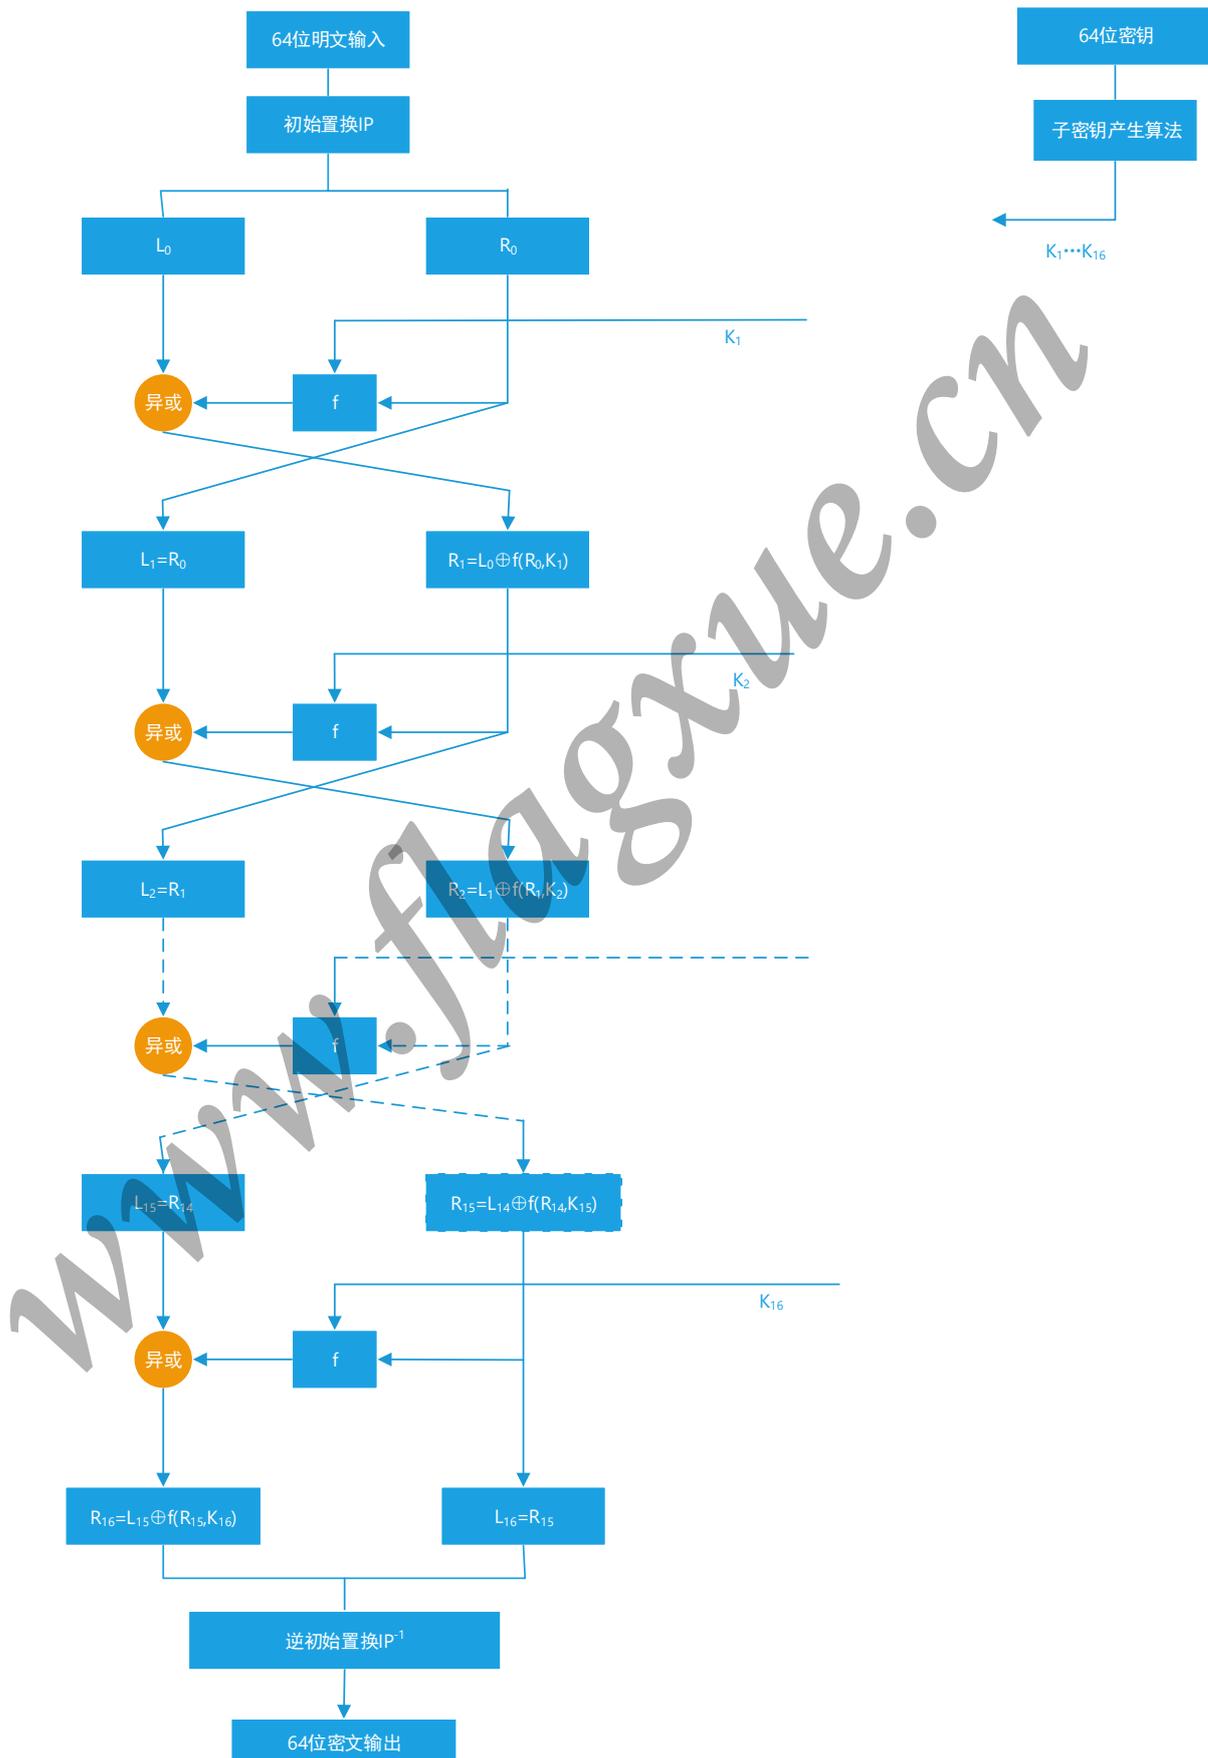

实验思路：

实验最关键的方面在于对明文的分块处理、二进制转化、盒子操作、以及子密钥的产生和十六次加密迭代使用。因此，在进行实验时目标明确，先处理密钥，生成 16 个 48 位的子密钥，再处理明文，接着实现盒子操作与加密函数 f ，然后迭代 16 次，产生 64 位数据组，之后对数据组进行处理后，经过逆初始置换，得到 64 位明文，至此一组加密过程全部结束。在本实验中，定义以下规则：(1) 将初始明文/密文分组并依次转化为二进制比特流之后，若分组内比特流长度不足 64 位，则补 0。(2) 对密钥的操作处理：输入 7 位英文字符，得到其对应的 ASCII 码，将 ASCII 码用二进制表示，最终得到 56 位二进制比特流，将此作为 DES 的 56 位密钥。之后在第 8, 16, 24, 32, 40, 48, 56, 64 位处插入奇偶校验位，合成 64 位密钥。

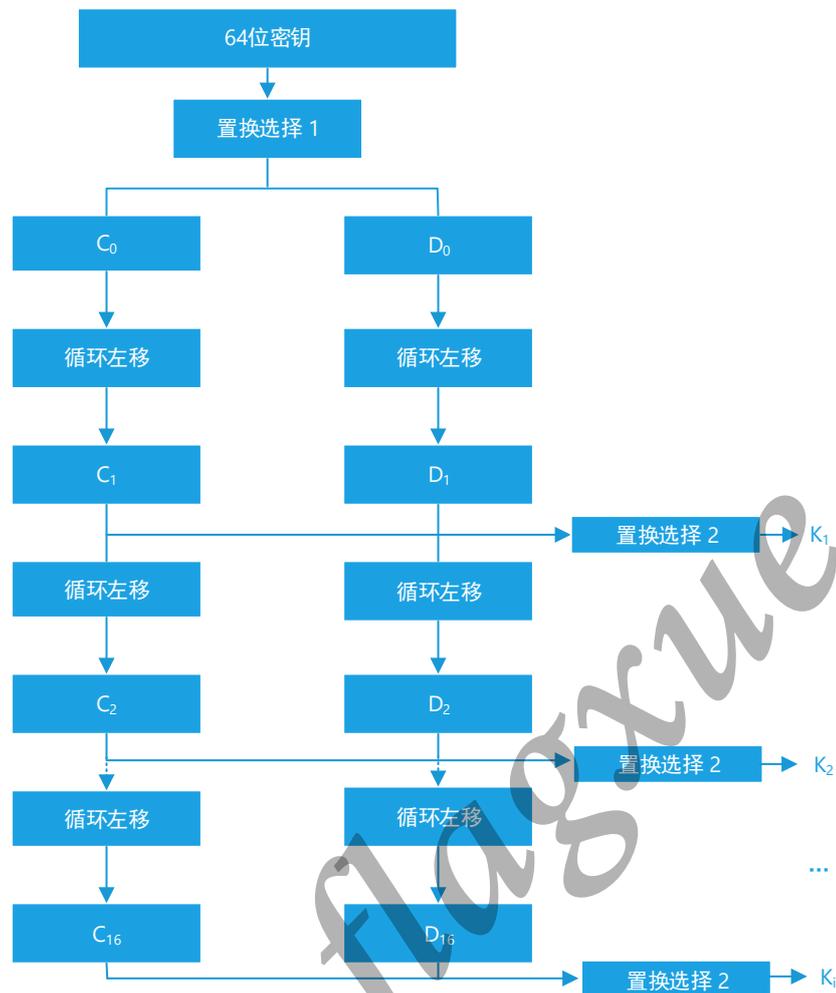

程序框图：(见下页)

www.flagzue.cn

DES 的整体结构:

子密钥的产生:

四、实验的步骤与调试方法

实验步骤:

- (1) 64 位密钥经过子密钥产生算法产生 16 个子密钥: K_1, K_2, \dots, K_{16} , 分别供第一次, 第二次, \dots , 第十六次加密迭代使用。
- (2) 64 位明文首先经过初始置换 IP (Initial permutation), 将数据打乱重新排列并分成左右两半。左边 32 位构成 L_0 , 右边 32 位构成 R_0 。
- (3) 由加密函数 f 实现子密钥 K_1 对 R_0 的加密, 结果为 32 位的数据组 $f(R_0, K_1)$ 。 $f(R_0, K_1)$ 再与 L_0 模 2 相加, 又得到一个 32 位的数据组 $L_0 \oplus f(R_0, K_1)$ 。以 $L_0 \oplus f(R_0, K_1)$ 作为第二次加密迭代的 R_1 , 以 R_0 作为第二次加密迭代的 L_1 。至此, 第一次加密迭代结束。
- (4) 第二次加密迭代至第十六次加密迭代分别用于子密钥 K_2, \dots, K_{16} 进行, 其过程与第一次加密迭代相同。

(5)第十六次加密迭代结束后，产生一个 64 位的数组。以其左边 32 位作为 R_{16} ，以其右边 32 位作为 L_{16} ，两者合并再经过逆初始置换 IP^{-1} ，将数据重新排列，便得到 64 位密文。至此加密过程全部结束。

步骤	说明	调用函数
1	加密/解密主函数	main()
2	检查输入的密钥是否合法	Check(string)
3	从文件读取加密	readFileIntoString(char *)
4	实现明/密文块和二进制转化	plainTrans(string, int, int (&)[][64], int)
5	密钥二进制转换	keyTrans(string, int[64])
6	构造子密钥	makeKey(int *, int (&)[16][48], int)
7	DES 初始置换	initial(int (&)[][64], int (&)[][64], string)
8	扩展置换(EBox)	funEBox(int [48], int [32])
9	代替函数组(SBox)	funSBox(int[][48], int[48], int[32], int)
10	置换运算(PBox)	funPBox(int[32], int[32])
11	逆初始置换 IP^{-1}	funFinalTP(int[32], int[32], int[64], int, int (&)[][64])
12	输出加/解密结果并储存到文件	outputchar(int (&)[800][64], int, int)

调试方法:

- (1)从文件读取解密时，发现不能将加密后的密文全部读取，只能读取少部分密文。通过分析，可能是加密的文件中存在因为加密而产生的文件终止符 (EOF), 因此必须想办法将其转化为可读的二进制形式。在编程过程中，通过二进制读取文件的方式读取文件可解决此问题。读取格式如下：`ifstream ifile(filename, _IOSbinary)`，其中 `_IOSbinary` 指以二进制方式打开文件。
- (2)程序编写完成后，在运行程序时发现，当输入的明文过多时(大于 500 字符)会出现程序异常退出的情况。通过分析，发现是变量空间分配不足导致的。将变量空间扩大即可解决此问题。

五、实验数据与实验结果

加密:

实验数据:

752         cout << templeft[flag];
753     }
754
755     cout << endl << "RP(" << j + 1 << "): ";
756     for (flag = 0; flag < 32; flag++) {
757         cout << tempright[flag];
758     }
759     cout << endl;
760 }
761 funFinalTP(templeft, tempright, finalTrans, i, finalresult);
762 }
763 cout << endl << "-----Final Result -----" << endl;
764 cout << endl << "Stream Ciphertext: " << endl << endl;
765 for (i = 0; i < block + 1; i++) {
766     for (j = 0; j < 64; j++) {
767         cout << finalresult[i][j];
768     }
769     cout << endl;
770 }
771
772 //由ASCII码输出字符
773 outputchar(finalresult, i, way);
774 system("PAUSE");
775 }
776
777 }
778

```

七、思考题

1. DES 的原理是什么?

答: DES 是分组加密算法, 明文按 64 位进行分组, 有效密钥长度为 56 位。通过将分组后的明文组和 56 位的密钥按位替代或置换的方法形成密文组。

2. DES 使用多少位密钥?

答: DES 使用 56 位密钥。

3. DES 对明文分块的单位是多少?

答: DES 算法中明文以 64 位进行分组。

4. DES 对每一个数据块加密的轮次是多少?

答: DES 对每一个数据块加密的轮次为 16 轮。

5. 简单描述 EBox 的操作过程。

答: Ebox 是一种扩展运算, 对 32 位的数据组的各位按照一定的顺序进行选择 and 排列, 产生一个 48 位的结果。

6. 简单描述 SBox 的操作过程。

答: Sbox 将 48 比特向量通过非线性映射变为 32 比特向量。首先, 48 比特的向量被分为 8 个 6 比特分组, 8 个分组在 8 个不同的非线性 Sbox 的作用下被转变为 8 个 4 比特分组, 其中每个 Sbox 都将 6 比特输入映射为 4 比特输出。

7. 简单描述 PBox 的操作过程。

答: Pbox 是一种置换运算, 把 Sbox 输出的 32 位数据打乱重排, 得到 32 位的加密函数输出。用 P 置换来提供扩散, 把 S 盒的混淆作用扩散开来。

八、结束语

通过实践课程, 我深入了解了数据加密标准 (DES) 的加密原理及算法步骤, 加深了我对分组密码的理解, 在实践过程中不仅验证了理论知识, 还加强了实验手段和实践技能, 培养了自主分析问题、解决问题、应用知识的能力和创新能力, 获益匪浅。我认为实践课程对深入理解密码学的内涵有很大帮助, 理论与实践相结合, 对我的综合素质有很大的提升。

实验成绩

考查内容	分数	得分
做好实验内容的预习，写出预习报告	10	
了解实验题目的调试方法	10	
按实验要求预先设计好程序	10	
认真记录实验数据并分析实验结果	10	
实验后按要求书写实验报告，记录实验用数据及运行结果	30	
创新能力强，在实验中设计的程序有一定的通用性，算法优化	20	
实验过程中，具有严谨的学习态度，认真、踏实、一丝不苟的科学作风	10
